**Abstract -** Friction stir welding is a new solid state welding process for joining metallic alloys and it is useful in serve industries for joining aluminium, magnesium and copper alloys. The various parameter such as rotational speed, transverse speed and tool tilt angle play important roles in FSW process and quality weld. The aim of this study is to know the relation between the effects of different transvers speed and tool profile on the weld quality of AA6061-T6 aluminium. The geometry of the pin tool along with the process parameters plays an important role in dictating the path that the material takes. The tool geometry was carefully chosen and fabricated to have an early flat welded interface pin profile. In this work, a narrow gap has been made to analyze the effect of various tool profiles on mechanical properties of aluminium alloy. Various tool profile shave been used to fabricate joints by using varying thickness work piece of Aluminium alloy. Numerical techniques particularly, the finite element method for the simulation of FSW for thermal, mechanical and thermo-mechanical modelling has been investigated. The current studies also aim to understand mechanical properties during the FSW.

**Key Words:** Friction Stir Welding, Transient Thermal Analysis, Al6061, Process parameter, Tool Profile

### 1. INTRODUCTION

Friction Stir Welding process is relatively a new joining process that is presently attracting considerable interest. Since the joint can be obtained below the melting temperature, this method is suitable for joining a number of materials those are extremely difficult to be welded by conventional fusion techniques.

The process is solid state in nature and relies on the localized forging of the weld zone to produce the joint. A constantly rotated non-consumable cylindrical tool with a profiled probe is transversely fed at a constant rate into a butt joint between two clamped pieces of butted material. The probe is slightly shorter than the weld depth required, with the tool shoulder riding atop the work surface.

Frictional heat is generated between the wear-resistant welding components and the workpieces. This heat, along with that generated by the mechanical mixing process and the adiabatic heat within the material, causes the stirred material to soften without melting.

FSW is actually performed in different steps as shown in figure 1. The probe primary function is to mix the material under the tool shoulder, which can be hardened by threads. First, the probe is plunged into the joint formed by the two sheets to be welded, until the shoulder gets in contact. As the tool rotates at a high velocity, the sheets are heated up by plastic deformation and friction. As the pin moves forward, a special profile on its leading face forces plasticized material to the rear where clamping force assists in a forged consolidation of the weld. This process of the tool traversing along the weld line in a plasticized tubular shaft of metal results in severe solid state deformation involving dynamic recrystallization of the base material. Figure 1 shows process of tool traversing along the weld line.[1],[2]

### 1.1 Keyof Benefits

In contrast to the traditional friction welding, which is usually performed on small axisymmetric parts that can be rotated and pushed against each other to form a joint, FSW can be applied to various types of joints like butt joints, lap joints, T-joints and fillet joints.

**Table-1:**ThekeybenefitsofFSWProcess

| Metal lurgical benefits                          | Envir onmental Benefits                                       | Energy benefits          |
|--|---|--------------------------|
| Solidphase process                               | No shielding gas required                                     | Reductioninweight        |

### 1.2 Comparisonoffrictionstirweldingtotherweldingprocesses

Comparison of FSW to other welding processes is typically done within the context of justifying the use of the process over other, more conventional techniques. Successful application of FSW depends upon a clear understanding of the characteristics of the process, so favorable technical and economic justification can be developed.

The unique, favorable characteristics of

FSW compared to traditional arc welding methods provides several advantages for technical justification for use of the process.[3],[4]

The main points for technical justification of FSW compared to arc welding processes are;

- Improved weldability
- Reduced distortion
- Reduced residual stress

**Table-2:** Light duty lathe machine specification

| Sr no | Features              | Values     |
|-------|-----------------------|------------|
| 1     | Swingoverbed          | 90mm       |
| 2     | Swingovercarriage     | 45mm       |
| 3     | Distancebetweencenter | 430mm      |
| 4     | Overalllength         | 820mm      |
| 5     | Overallwidth          | 220mm      |

| 7     | Shippingweight        | 140kg      |
| 8     | Holethroughspindle    | 10mm       |
| 9     | Spindlespeedrange     | 575-900rpm |

- Improved cosmetic performance
- Elimination of undermatched filler metal
- Improved static strength and ductility
- Mechanized process
- High robustness and few process variables

## 2. DESIGN APPROACH

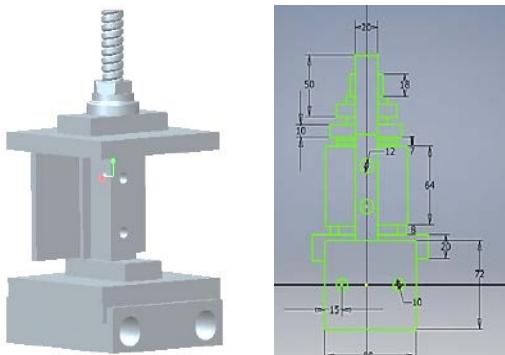

Generally, Friction stir welding is performed on the Milling or Radial cum drilling machine. But our main objective is to perform operation onto Lathe Machine. So forth an attachment is required to hold a welding plate on a lathe machine.[9],[10]

### 2.1 Basic Requirement of machine:

The performance test on Lathe machine for the FSW technique is analyzed for the different parameters.

### 2.1.1 Latheattachment

Now for holding a welding plate on the machine an additional attachment is required for mounting purpose. Figure 3 shows CAD Geometrical view of lathe attachment for holding of welding plate.

**Fig-3:**  
3: CAD Geometrical view of Lathe Attachment (All dimensions are in mm)

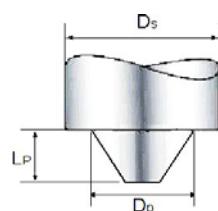

**TABLE 3.** Tool design parameter [15]

| Weld tool Geometry | AL     | TI      | Steel (HMTM) |
|--------------------|--------|---------|--------------|
| DS/DP              | 2.4    | 1.2-3.8 | 2.3-2.4      |
| DP/LP              | 1.5    | 1.4-1.9 | 1.7-2.0      |
| Pinsurface         | Treads | Smooth  | Smooth       |
| Taper              | 0      | 30-60   | 30-60        |

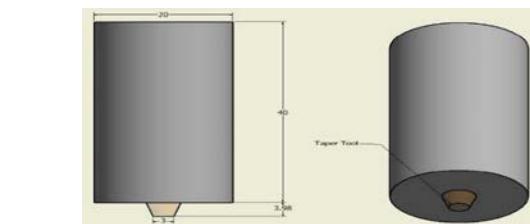

### 2.2 Basic requirement of tool geometry

A novel pin is designed for friction stir welding tools that can penetrate more deeply into work pieces to form a thicker weld joint without overloading the tool. The pin is provided with cylindrical and taper faces on the surface of the tool. The diameter of the tool shoulder ( $D_s$ ) and the diameter of the tool pin ( $D_p$ ) are chosen based on the literature survey. The shoulder of the tool is designed to produce heat on the surface of the work pieces. The tool shoulder accounts for majority of the deformation and frictional heat generation between the work pieces. Due to large surface area, friction increases, which in turn increases the amount of heat generated. [6], [7], [8]

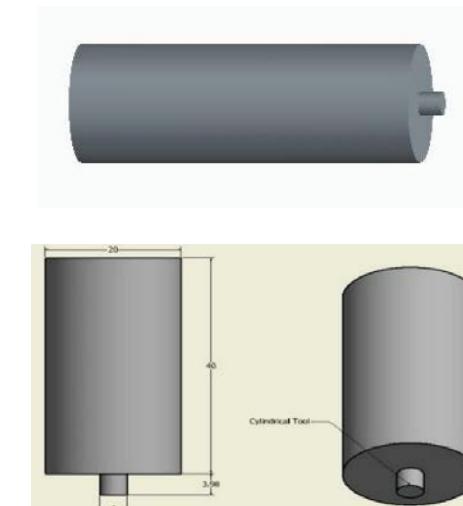

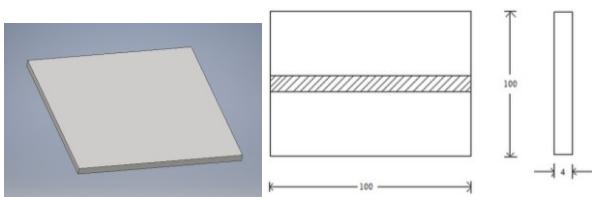

**Fig-4.** Tool Geometry

**Fig-5:**  
5: CAD geometry of Taper Tool (All dimensions are in mm)

❖ Cylindrical tool:

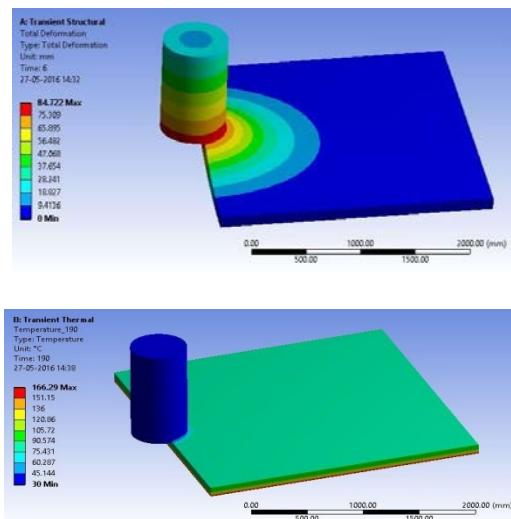

**Fig-7:**CAD Geometrical Dimension (All dimensions are in mm)

### 3. SIMULATION BASED APPROACH

Three-dimensional thermomechanical model and the thermomechanical effect of the welded material is developed for the FSW of an Al-alloy, in order to build qualitative framework to understand the thermomechanical process in FSW. In this analysis work below figure shows the total deformation and temperature graph for a cylindrical tool geometry. The prediction and the measurement show that the maximum temperature gradients in longitudinal and lateral directions are located just beyond the shoulder edge. To simulate this kind of welding process, a fully coupled thermo-mechanical solution has been adopted to simulate the FSW process. [11], [13]

**Fig-8:**Total deformation and Temperature profile

Figure 8 shows the Total deformation and temperature profiles in the work piece during the welding operation for  $N_2 = 900$  rpm;  $T_2 = 3.16$  mm/min and for a cylindrical tool profile for the size of 4 mm thickness plate. [14], [16]

are discussed below which are effecting for the Analysis on FSW. [15]

#### 4.1 Process parameter

### 4. EXPERIMENTAL WORK

Experimental setup was recognized using a light-duty lathe machine. No extra set up is required for friction stir welding except tool and fixture, so as to place piece in proper position during welding. The different process parameters The various process parameters play important roles in FSW process and quality weld.

**Table 4:**Main FSW process variables

| Tooldesign variables      | Machine variables     | Other variables      |
|---------------------------|-----------------------|----------------------|
| Shoulder and pin material | Welding speed         | Anvil material       |
| Shoulder diameter         | Spindle speed         | Anvil size           |
| Pin diameter              | Plunge force or depth | Workpiece size       |
| Pin length                |                       |                      |
| Thread pitch              |                       |                      |
| Feature geometry          | Tool tilt angle       | Workpiece properties |

There are many parameters are effecting for the analysis on friction stir welding as shown in Table 4. As many parameters are important in the friction stir welding but in this experiment main two parameters are selected for analysis by using lathe machine;

- (1) Tool speed
- (2) Transverse speed

The proper choice of tool rotation and transverse speed will produce a good quality weld. The material use for base plate is Al alloy 6061 and the material use for the tool geometry is EN8.

#### 4.2 Process step for friction stir welding on lathe machine

The experimental study includes the butt joining of aluminum plates. The welding

**Fig-9:** Process steps for FSW Experiment

In the present work, different FSW butt welds were obtained by varying the process parameters within the range and the optimal values are drawn based on the trend of the values. In this experiment it is observed that the process parameters like tool design, tool rotational speed, welding speed and materials are the main parameters to produce the effective butt joint by friction stir welding.[17]

#### 4.3 Observation table

**Table 5:** Experiment data

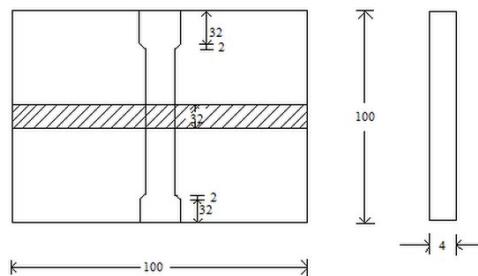

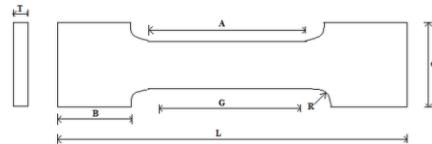

| Sr No | Material AA-6061 | RPM (n) | Transverse Speed (mm/min) | Pas | Material size(mm) |   |
|-------|------------------|---------|---------------------------|-----|-------------------|---|
| 1     | Plateno: 2       | N2=900  | T2=3.16 mm/min            | P1  | S2=100*45*4       | C |
| 2     | Plateno: 9       | N9=900  | T9=3.37 mm/min            | P2  | S9=100*45*6       | T |
| 3     | Plateno: 8       | N8=575  | T8=7.35 mm/min            | P1  | S8=100*45*4       | L |
| 4     | Plateno: 3       | N3=575  | T3=8.16 mm/min            | P2  | S3=92*45*6        | A |
| 5     | Plateno: 6       | N6=900  | T6=4.41 mm/min            | P1  | S6=100*45*4       | G |
| 6     | Plateno: 4       | N4=900  | T4=6.15 mm/min            | P2  | S4=100*45*6       | R |
| 7     | Plateno: 7       | N7=575  | T7=4.50 mm/min            | P1  | S7=100*45*4       | B |
| 8     | Plateno: 5       | N5=575  | T5=4.49 mm/min            | P2  | S5=100*45*6       | C |

Plateno 2: (P1N2T2S2C); Cylindrical Tool = C; Tapper Tool = t; RPM = N; Transverse speed = T; Material size = S; Single pass = P1; Double pass = P2

#### 4.4 Tensile Tests:-

Tensile strength, along with elastic modulus and corrosion resistance, is an important parameter of engineering materials used in structures and mechanical devices.

- *Tensile test specimen geometry*

**Fig+++++**

**10:** Tensile test specimen (All dimensions are in mm)

- *Subsize specimen:*

t: Thickness: Thick of

material

C: plate R: Radius of fillet: 6mm

L: overall length: 100mm

A: Length of reduced section: 32mm

B: Length of grip section: 32mm

C: Width of grip section: 10mm

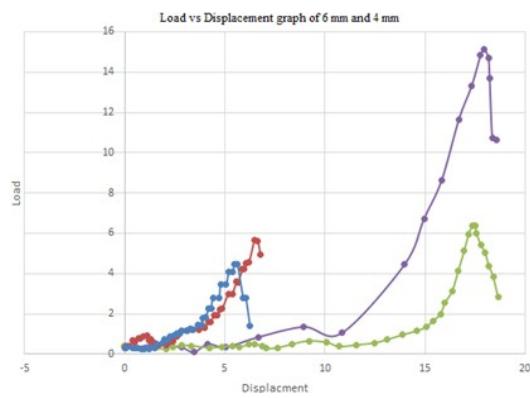

#### 4.5 Tested plate and results

The process parameters selected were mainly tool rotational speed, welding speed and tool geometry etc. Tests are performed as per the ASTM Standards at TCR Advance Engineering at Vadodara. A machined specimen is placed in the testing machine and load is applied to measure the resistance of a material. The result for tensile strength for sample specimen is shown in Table 6.

**Table6:**Tensilestrengthofsamplespecimen

| Srno | Plateno | Force (KN) | Area (mm <sup>2</sup> ) | Ultimate tensilestrength(N/mm <sup>2</sup> ) |
|------|---------|------------|-------------------------|--|

Figure12showsthe load vs displacement graph for varying thickness of plate on Tensile strength.

## 5. CONCLUSION

Important process parameters that control the quality of the weld are rotation speed (575 - 900 rpm) and traverse speed (3.16-8.16 mm/min) were performed to obtain defect free welded joints.

The following various conclusions summarize the present paper;

- From this investigation, it has been found that tool profile cylindrical tool, transvers speed 3.37 mm/min and rotational speed is 900 rpm produced good tensile strength.
- Mechanical properties of the joints increases with increase in tool rotational speed and reaches maximum at 500 to 575 rpm but again deceases with further increase in tool rotational speed.
- The heat input from the tool shoulder was sumed to be the frictional heat. The coefficient of friction was

continuously adjusted to keep the calculated temperature from exceeding the material melting point.

- Increase in pin length decreases penetration depth on the back side of welded plate. It is also observed that more than 6 mm thickness of workpiece is possible to weld by friction stir welding butt. The condition is to design a different tool for different thickness. While designing tool, the tool tip length should be less than the thickness of the base material i.e. less than 0.25 to 0.8 times of the base material thickness.
